NON - LINEAR BEHAVIOUR

LINEAR BEHAVIOUR - assumes small strains and strain rates

SOLIDS - Hooke's law

FLUIDS - Newton's law

VISCOELASTICITY - non linear response as a function of time modeled by assuming a linear relationship between stress and strain. Simple mechanical models were constructed by combining linear elastic and viscous elements

NON - LINEAR BEHAVIOUR - larger strains and strain rates

SOLIDS - will only consider rubber elasticity

FLUIDS AND VISCOELASTIC MATERIALS - some qualitative observations
RUBBER ELASTICITY

THERMODYNAMICS REVISTED

\[ F = E - TS \]

\[ f = \left[ \frac{\partial E}{\partial l} \right]_V, T - T \left[ \frac{\partial S}{\partial l} \right]_V, T \]

For crystalline and glassy solids

\[ f \sim \left[ \frac{\partial E}{\partial l} \right]_V, T \]

For elastomer networks

\[ f \sim - T \left[ \frac{\partial S}{\partial l} \right]_V, T \]
STRETCHING OF A SINGLE CHAIN

Stretch along z direction

$$\Omega = P(R) = P(x, y, z) \left[ \frac{\beta^2}{\pi} \right]^{3/2} \beta^2 \mathcal{P}(\cdot)$$

Probability distribution
Is a Gaussian function
For large N

$$\beta^2 = \frac{3}{2Nl^2} = \frac{3}{2 \langle R_0^2 \rangle}$$

$$\Omega = P(R) = P(x, y, z) \left[ \frac{\beta^2}{\pi} \right]^{3/2} \beta^2 \mathcal{P}(\cdot + y + z)$$

$$S = k \ln \Omega$$

$$\Omega = P(R) = P(x, y, z) = P(0, 0, z)$$

$$S = \text{constant} - \beta k z^2$$

$$f = 2k\beta^2 z \quad \text{Hooke's law!}$$

$$\text{Modulus} \sim T!$$
We need to consider the stretching of a cross-linked network. Real networks have defects. We will consider the stretching of a model network where the functionality of all the cross link points is identical, there are no dangling ends, and the number of segments between all the junction points is the same.
Define extension ratio

\[ \lambda = \frac{1}{\lambda_0} \]

Assume no change in Volume upon stretching

\[ \lambda_1 \lambda_2 \lambda_3 = 1 \]

In the unstrained state

\[ R_0^2 = x_0^2 + y_0^2 + z_0^2 \]

Hence

\[ s_0 = \text{constant} \cdot \frac{2}{\lambda_0} \left( x_0^2 + y_0^2 + z_0^2 \right) \]
RUBBER ELASTICITY THEORY

Affine assumption - chain deforms in exact proportion to Sample as a whole (parent cube on previous overhead)

\[ x = \lambda_1 x_0, \quad y = \lambda_2 y_0, \quad z = \lambda_3 z_0 \]

\[ s = \text{constant} \cdot k^2 \left( x^2 + y^2 + z^2 \right) \]

\[ = \text{constant} \cdot k^2 \left( \frac{x^2}{\lambda_1} + \frac{y^2}{\lambda_2} + \frac{z^2}{\lambda_3} \right) \]

\[ \Delta s = \text{constant} \cdot k^2 \left( (\lambda_1^2 - 1)x_0^2 + (\lambda_2^2 - 1)y_0^2 + (\lambda_3^2 - 1)z_0^2 \right) \]

Using \[ S = \sum \Delta s \]

And

\[ \sum R_0^2 = \Sigma x_0^2 + \Sigma y_0^2 + \Sigma x_0^2 \]

\[ (1/3) \sum R_0^2 = \Sigma x_0^2 = \Sigma y_0^2 = \Sigma x_0^2 \]

\[ \Sigma R_0^2 = N \langle R^2 \rangle \]

Obtain

\[ \Delta S = - (1/2) N k^2 \left( \lambda_1^2 + \lambda_2^2 + \lambda_3^2 - 3 \right) \]
RUBBER ELASTICITY THEORY

\[ \Delta S = -(1/2)Nk(\lambda_1^2 + \lambda_2^2 + \lambda_3^2 - 3) \]

**Constant volume assumption**

\[ \lambda_1 \lambda_2 \lambda_3 = 1 \]

For simple extension in the \( x \) direction the affine Assumption gives

\[ \lambda_2 = \lambda_3 \]
\[ \lambda_1 = \frac{1}{\lambda_3 \lambda_2} \]

Substituting

\[ \Delta S = -(1/2)Nk(\lambda_1^2 + 2\lambda_1^2 - 3) \]

Hence

\[ f = NkT(\lambda_1^2 - 1\lambda_1^2) \]  

or  

\[ f = E(\lambda_1^2 - 1\lambda_1^2) \text{ where } E = NkT \]

**Question** — what would happen to a stretched rubber sample upon heating?
RUBBER ELASTICITY THEORY
- comparison to experiment

Agreement not bad at strains up to ~ 300%, but the semi-empirical Mooney–Rivlin equation provides a better fit

\[ f = NkT(\lambda_1 - 1\lambda_1^2) \]

\[ \sigma = 2 (\zeta + 2\lambda_1) (\lambda_1 - 1\lambda_1^2) \]

More advanced theories (e.g. Flory Constrained Junction Model) does a better job, but this is beyond the scope of this course.
